### Desire a simple WTLS solution

- Know that WLS solution is biased, but WTLS demands too much computation to use in practical BMS
- Have seen proportional-uncertainty version of WTLS—which we call TLS—that is feasible to implement: but, uncertainties are not necessarily proportional in practice
- We desire solution that approximates WTLS problem but allows  $\sigma_{x_i}^2$  and  $\sigma_{y_i}^2$  to be nonproportional, but which yields a recursive solution for feasible implementation in an embedded system
- In this lesson, you will learn an approach we can take, based on geometry of WTLS solution

1.3.3: Defining geometry for approximate full solution to weighted total least squares

#### WTLS geometry (1/2)

- Figure shows WTLS geometry, motivates approximate solution to be developed
- Left frame shows relationship between data point  $(x_i, y_i)$  and its optimized map  $(X_i, Y_i)$  on  $Y_i = \widehat{Q} X_i$  when  $\sigma_{x_i}^2$  and  $\sigma_{y_i}^2$  are arbitrary
  - $\Box$  The error bars on each data point illustrate the uncertainties in each dimension, which are proportional to  $\sigma_{x_i}$  and  $\sigma_{v_i}$

4.3.3: Defining geometry for approximate full solution to weighted total least squares

# WTLS geometry (2/2)

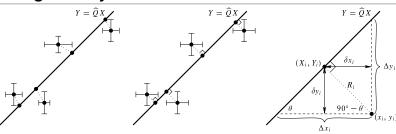

- We see that the distance between  $x_i$  and  $X_i$  is not necessarily equal to the distance between  $y_i$  and  $Y_i$ —depends on respective error bounds
- If quality of  $x_i$  is better (poorer) than quality of  $y_i$ , distance to its map  $X_i$  should be shorter (greater) than the distance from  $y_i$  to its map  $Y_i$

4.3.3: Defining geometry for approximate full solution to weighted total least squares

#### TLS geometry

- Middle frame shows relationship between data point  $(x_i, y_i)$  and its optimized map  $(X_i, Y_i)$  on  $Y_i = \widehat{Q} X_i$  when  $\sigma_{x_i}^2$  and  $\sigma_{y_i}^2$  are equal
- Distance between  $x_i$  and  $X_i$  is equal to distance between  $y_i$  and  $Y_i$ , and line joining data point  $(x_i, y_i)$  and  $(X_i, Y_i)$  is perpendicular to the line  $Y_i = \widehat{Q} X_i$ 
  - $\Box$  If  $\sigma_{x_i}$  and  $\sigma_{y_i}$  are unequal but proportional, x- or y-axis may be scaled to yield transformed data points with equal variances, and hence same idea applies

4.3.3: Defining geometry for approximate full solution to weighted total least squares

#### Approximated geometry (1/2)

- Right frame illustrates definitions that will be used to derive an approximate weighted total least squares (AWTLS) solution
- Motivated by TLS, we enforce that line joining data point  $(x_i, y_i)$  and  $(X_i, Y_i)$  be perpendicular to line  $Y_i = \widehat{Q} X_i$ —will result in a recursive solution

4.3.3: Defining geometry for approximate full solution to weighted total least squares

# Approximated geometry (2/2)

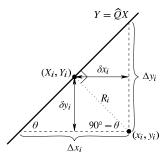

- However, as with the WTLS solution, we weight distance between  $x_i$  and  $X_i$  differently from distance between  $y_i$  and  $Y_i$  in optimization cost function
- This will give a better total capacity estimate than TLS when the uncertainties on  $x_i$  and  $y_i$  are not proportional

### **Summary**

- WTLS solution maps  $(x_i, y_i)$  to  $(X_i, Y_i)$  on  $Y = \widehat{Q}X$ with nonperpendicular line
  - □ Optimal but not practical to implement
- TLS maps with perpendicular line
  - $\ \Box$  Optimal only for proportional  $\sigma_{x_i}$  and  $\sigma_{y_i}$  but practical
- Will use observation of orthogonality to propose suboptimal mapping  $(x_i, y_i)$  to  $(X_i, Y_i)$  that is perpendicular, but also weights uncertainties in  $\sigma_{x_i}$  and  $\sigma_{y_i}$
- Will continue to use geometry from figure to right as we proceed beyond this point
